

## AIDS Lab Experiment 08

**Aim:** To implement recommendation system on your dataset using the following machine learning techniques.

- o Regression
- o Classification
- o Clustering
- o Decision tree
- o Anomaly detection
- o Dimensionality Reduction
- o Ensemble Methods

### What is Collaborative Filtering?

Collaborative Filtering is a recommendation technique that predicts a user's interests by analyzing preferences from similar users or items. It's widely used in platforms like Netflix, Amazon, and UberEats for personalized recommendations.

There are two main types:

1. User-Based Collaborative Filtering:
  - o Recommends items liked by similar users.
2. Item-Based Collaborative Filtering:
  - o Recommends items that are similar to what the user already liked.

### Matrix Factorization

Collaborative filtering often involves creating a User-Item Ratings Matrix, which is sparse (many missing values). Matrix Factorization techniques (like SVD) are used to:

- Reduce dimensionality.
- Discover latent features (hidden patterns).
- Predict missing ratings.

### Singular Value Decomposition (SVD)

SVD decomposes a user-item matrix  $R$  into three matrices:

$$R \approx U \cdot \Sigma \cdot V^T \quad \text{or} \quad R \approx U \cdot \Sigma \cdot V^T$$

- $U$ : User-feature matrix
- $\Sigma$ : Diagonal matrix of singular values
- $V^T$ : Restaurant-feature matrix

SVD helps us represent users and restaurants in a shared latent space, allowing us to compute predicted ratings and make recommendations.

## Collaborative Filtering Breakdown (UberEats Dataset)

**Step 1: Import Required Libraries**

```
import pandas as pd
```

```
import numpy as np
```

```
from sklearn.decomposition import TruncatedSVD
```

- pandas: To load and manipulate the dataset.
- numpy: For matrix computations.
- TruncatedSVD: A dimensionality reduction technique used for matrix factorization.

```
>>> <class 'pandas.core.frame.DataFrame'>
RangeIndex: 1059 entries, 0 to 1058
Data columns (total 27 columns):
 #   Column                Non-Null Count  Dtype
---  -
 0   city                  1058 non-null   object
 1   state                 1059 non-null   object
 2   zipcode               1056 non-null   object
 3   address               1059 non-null   object
 4   loc_name              1059 non-null   object
 5   loc_number            1059 non-null   object
 6   url                   1059 non-null   object
 7   promotion             121 non-null     object
 8   latitude              1059 non-null   float64
 9   longitude             1059 non-null   float64
10   is_open               1059 non-null   bool
11   closed_message        1045 non-null   object
12   delivery_fee          3 non-null      float64
13   delivery_time         14 non-null     object
14   review_count          393 non-null    float64
15   review_rating         443 non-null    float64
16   price_bucket          909 non-null    object
17   img1                  1006 non-null   object
18   img2                  1006 non-null   object
19   img3                  1006 non-null   object
20   img4                  1006 non-null   object
21   img5                  1006 non-null   object
22   ...                   ...
```

**Step 2: Load the Cleaned UberEats Dataset**

```
file_path = "UberEats_Cleaned_Dataset.csv"
```

```
df = pd.read_csv(file_path)
```

- Loads the cleaned dataset containing user reviews and ratings.

**Step 3: Create the User-Item Matrix**

```
user_item_matrix = df.pivot_table(index='User_ID', columns='Restaurant', values='Rating',
fill_value=0)
```

- Creates a matrix where:
  - Rows = Users
  - Columns = Restaurants
  - Values = Ratings

- Missing ratings are filled with 0 (assumes user hasn't rated those restaurants).

#### Step 4: Apply Singular Value Decomposition (SVD)

```
svd = TruncatedSVD(n_components=10, random_state=42)
```

```
matrix_svd = svd.fit_transform(user_item_matrix)
```

- SVD breaks the user-item matrix into lower-dimensional matrices.
- `n_components=10` means we reduce to 10 latent features (like cuisine type, price preference, etc.).

#### Step 5: Define the Recommendation Function

```
def get_recommendations(user_id, n=5):
```

```
    if user_id not in user_item_matrix.index:
        return "User not found."
```

```
    user_index = user_item_matrix.index.get_loc(user_id)
```

```
    user_ratings = matrix_svd[user_index]
```

```
    restaurant_scores = np.dot(user_ratings, svd.components_)
```

```
recommended_restaurants = np.argsort(restaurant_scores)[:,-1][:n]  
return user_item_matrix.columns[recommended_restaurants]
```

- Input: A user ID and number of recommendations.
- Output: Top-N restaurants based on predicted ratings.
- Steps inside function:
  - Get the user's vector in the SVD-reduced space.
  - Compute similarity scores with all restaurants.
  - Return the restaurants with the highest scores.

### Step 6: Example Usage

```
user_id = "User_2"  
recommended = get_recommendations(user_id, n=5)  
print(f"Top 5 Recommended Restaurants for {user_id}:")  
print(recommended)
```

- Replace "User\_2" with any user present in the dataset.
- Prints out top 5 personalized recommendations.

```
Top 5 Recommended Restaurants for User_2:  
Index(['The Purple Onion (Inverness)', 'Hong Kong Seafood',  
      'La Paz (Euclid Ave)', 'Papa Johns (2480 Palomino Lane)',  
      'El Patron 4'],  
      dtype='object', name='Restaurant')
```

### Conclusion:

In this project, we successfully implemented a collaborative filtering-based recommendation system using Singular Value Decomposition (SVD) on the UberEats dataset. By transforming raw user review data into a structured user-item rating matrix, we were able to extract latent user preferences and restaurant features.

The SVD approach enabled us to overcome challenges of data sparsity and provided a powerful way to predict user interests, even when direct ratings were missing. The generated recommendations are personalized, relying on hidden patterns in user behavior rather than explicit restaurant characteristics.

This model is particularly effective for platforms like UberEats, where understanding user preferences from limited interactions is key. It demonstrates how machine learning and matrix factorization techniques can enhance user experience by offering relevant, data-driven suggestions.

Overall, the collaborative filtering approach has laid the foundation for a scalable recommendation engine that can adapt to more complex user data, incorporate real-time feedback, and evolve with user tastes.
